Abstract. Process-aware information systems ranging from generic workflow systems to dedicated enterprise information systems use work lists to offer so-called work items to users. The work list handlers typically show a sorted list of work items comparable to the way that e-mails are presented in most e-mail programs. Since the work list handler is the dominant interface between the system and its users, it is worthwhile to provide a more advanced graphical interface that uses context information about work items and users. This paper uses the "map metaphor" to visualise work items and resources (e.g., users) in a sophisticated manner. Moreover, based on "distance notions" work items are visualised differently. For example, urgent work items of a type that suits the user are highlighted. The underlying map and distance notions may be of a geographical nature (e.g., a map of a city of office building), but may also be based on the process design, organisational structures, social networks, due dates, calenders, etc. The approach presented in this paper is supported by a visualisation framework implemented in the context of YAWL. The framework is set up in such a way that it can easily be combined with other workflow systems.

Keywords: Process-aware Information Systems, work list visualisation, YAWL

1 Introduction

Originally, *Process-Aware Information Systems* (PAISs) [1] were mainly applied in the context of administrative processes. Later their application was extended to cross-organisational processes. Currently, PAISs are starting to be used for more flexible and/or pervasive processes, e.g., disaster management scenarios [2].

Independently on the application domain and underlying technology, a PAIS is driven by some process model. The model may be implicit or hidden, but the system supports the handling of cases in some (semi-)structured form. PAISs have also in common that they offer work to resources (typically people). The elementary pieces of work are called *work items*, e.g., "Approve travel request XYZ1234". These work items are offered to the users by the so-called *work*

list handler. This component takes care of work distribution and authorisation issues. Typically, PAISs use a so-called "pull mechanism", i.e., work is offered to all resources that qualify and the first resource to select it will be the only one executing it. To allow users to "pull the right work items in the right order", basic information is provided, e.g., task name, due date, etc. However, given the fact that the work list is the main interface of the PAIS with its users it seems important to provide support that goes beyond a sorted list of items. If work items are selected by less qualified users than necessary or if users select items in a non-optimal order, then the performance of the overall process is hampered. Assume the situation where multiple resources have overlapping roles and authorisations and that there are times where work is piling up (i.e., any normal business). In such a situation the questions listed below are relevant.

- "What is the most urgent work item I can perform?"
- "What work item is, geographically speaking, closest to me?"
- "Is there another resource that can perform this work item that is closer to it than me?"
- "Is it critical that I handle this work item or are there others that can also do this?"
- "How are the work items divided over the different departments?"

To our knowledge, commercial as well as open source PAISs present work lists simply as a list of work items each with a short textual description. Some products sort the work items in a work list using a certain priority scheme specified at design time and not updated at run time. To support the user in a better way and assist her in answering the above questions, we use *maps*. A map can be a geographical map (e.g., the map of a university's campus). But other maps can be used, e.g., process schema's, organisational diagrams, Gantt charts, etc. Work items can be visualised by dots on the map. By not fixing the type of map, but allowing this choice to be configurable, different types of relationships can be shown thus providing a deeper insight into the context of the work to be performed.

Work items are shown on maps. Moreover, for some maps also resources can be shown, e.g., the geographical position of a user. Besides the "map metaphor" we also use the "distance metaphor". Seen from the viewpoint of the user some work items are close while others are far away. This distance may be geographic, e.g., a field service engineer may be far away from a malfunctioning printer at the other side of the campus. However, many other distance metrics are possible. For example, one can support metrics capturing familiarity with certain types of work, levels of urgency, and organisational distance. It should be noted that the choice of metric is orthogonal to the choice of map thus providing a high degree of flexibility in context visualisation. Resources could for example opt to see a geographical map where work items, whose position is calculated based on a function supplied at design time, display their level of urgency.

This paper proposes different types of maps and distance metrics. Moreover, the framework has been implemented and integrated in YAWL.⁴ YAWL is an

⁴ www.yawlfoundation.org

open source workflow system based on the so-called workflow patterns. However, the framework and its implementation are set-up in such a way that it can easily be combined with other PAISs.

The paper is structured as follows. Section 2 discusses the state of the art in work list visualisation in PAISs, whereas Section 3 provides a detailed overview of the general framework. Section 4 focusses on the implementation of the framework, highlighting some design choices In Section 5 the framework is illustrated through a case study. Section 6 summarises the contributions of the paper and outlines avenues of future work aimed.

2 Related Work

Little work has been conducted in the field of work list visualisation. Visualisation techniques in the area of PAIS have predominantly been used to aid in the understanding of process schemas and their run time behaviour, e.g. through simulation [3] or process mining [4]. Although the value of business process visualisation is acknowledged, both in literature [5–8] and industry, little work has been done in the context of visualising work items.

The aforementioned body of work does not provide specific support for context-dependent work item selection. This is addressed though in the work by Brown and Paik [9], whose basic idea is close to the proposal of this paper. Images can be defined as maps and mappings can be specified between work items and these maps. Work items are visualised through the use of intuitive icons and the colour of work items changes according to their state. However, the approach chosen does not work so well in real-life scenarios where many work items may have the same position (especially in course-grained maps) as icons with the same position are placed alongside each other. This may lead to a situation where a map is completely obscured by its work items. In our approach, these items are coalesced in a single dot of which the size is proportionate to their number. By gradually zooming in on such a dot, the individual work items cam become visible again. In addition, in [9] there is no concept similar to our distance notion, which is an ingredient that can provide significant assistance with work item selection to resources. Finally, the work of Brown and Paik does not take the visualisation of the positions of resources into account.

Also related is the work presented in [10], where proximity of work items is considered without discussing their visualisation.

Most PAISs present work lists as a simple enumeration of their work items, their textual descriptions, and possibly information about their priority and/or their deadlines. This holds both for open source products, as e.g. jBPM⁵ and Together Workflow⁶, as for commercial systems, such as SAP Netweaver⁷ and

 $^{^5~\}mathrm{jBPM}$ web site - http://www.jboss.com/products/jbpm

⁶ Together Workflow web site - http://www.together.at/together/prod/tws/

⁷ Netweaver web site - http://www.sap.com/usa/platform/netweaver

Flower⁸. An exception is TIBCO's iProcess Suite⁹ which provides a richer type of work list handler that partially addresses the problem of supporting resources with work item selection. For example, the work list handler can show the lengths of the work queues of other resources or position of work item on a geographic map at their location of execution. The iProcess Suite also supports a kind of look-head in the form of a list of "predicted" work items and their start times. One can also learn about projected deadline expirations and exception flows by expected durations specified at design time for the various tasks. Our visualisation framework is more accurate as it can take actual execution times of work items of a task into account through the use of log files when considering predictions for new work items of that task. Basically, the iProcess Suite provides support for some specific views (geographical position, deadline expiration) but these are isolated from each other. Our approach generalises over the type of maps (not just geographic) and unlike the iProcess Suite it is able to support multiple types of maps at the same time. The iProcess Suite is based on Google Maps while our framework does not rely on an external service for handling maps and positioning work items.

3 The General Framework

The proposed visualisation framework is based on a two-layer approach: (1) maps and (2) the visualisation of work items based on a distance notion. A work item is represented as a dot positioned along certain coordinates on a background map. A map is meant to capture a particular perspective of the context of the process. Since a work item can be associated with several perspectives, it can be visualised in several maps (at different positions). Maps can be designed as needed. When the use of a certain map is envisaged, the relationship between work items and their position on the map should be specified through a function determined at design time. Table 1 gives some examples of context views and the corresponding work item mapping.

Several active "views" can be supported whereby users can switch from one view to another. Resources can (optionally) see their own position on the map and work items are coloured according to the value of the applicable distance metric. Additionally, it may be helpful to show executing work items as well as the position of other resources. Naturally, these visualisations are governed by the authorisations that are in place.

Our framework assumes the generic lifecycle model as described in [11]. First, a work item is *created* indicating it is ready for distribution. The item is then *offered* to appropriate resources. A resource can commit to the execution of the item, after which it moves to the *allocated* state. The start of its execution leads it to the next state, *started*, after which it can successfully *complete*, it can be *suspended* (and subsequently *resumed*) or it can *fail* altogether. At run time a workflow engine informs the framework about the lifecyle states of work items.

	revenue of its execution is x and its cost is y . In this case one is best					
	off executing work items close to the x axis and far from the origin.					

3.1 Fundamentals

In this section the various notions used in our framework, e.g. work item and resource, are defined formally.

Definition 1 (Work item). A work item w is a tuple (c, t, i, y, e, l), where:

- -c is the identifier of the case that w belongs to.
- -t is the identifier of the task of which w is an instance.
- *i* is a unique instance number.
- y is the timestamp capturing when w moved to the "offered" state.
- -e is the (optional) deadline of w.
- I represents the (optional) GPS coordinates where w should be executed.

Dimensions y and I may be *undefined* in case work item w is not yet offered or no specific execution location exists respectively. The **e** value concerns timers which may be defined in YAWL processes. A process region may be associated with a timer. When the timer expires, the work items part of the region are cancelled. Note that a work item can potentially be a part of more than one cancellation region. In these cases, **e** is assumed as the latest possible completion time with respect to every cancellation region the work item is part of.

Definition 2 (Resource). A resource r is a pair (j, l), where:

- -j is the identifier of the resource.
- I represents the (optional) GPS coordinates where the resource is currently located.

The notation w_x is used to denote the projection on dimension x of work item w, while the notation r_y is used to denote the projection on dimension y of resource

r. For example, w_t yields the task of which work item w is an instance. Work items w' and w'' are considered to be *siblings* iff $w'_t = w''_t$. The set *Coordinates* consists of all possible coordinates. Elements of this set will be used to identify various positions on a given map.

Definition 3 (Position function). Let W and R be the set of work items and resources. Let M be the set of available maps. For each available map $m \in M$, there exists a function $position_m : W \cup R \not\rightarrow Coordinates$ which returns the current coordinates for work items and available resources on map m.

For a map $m \in M$, the function $position_m$ may be partial, since some elements of W and/or R may not have an associated position. Consider for example the case where a work item can be performed at any geographical location or where it does not really make sense to associate a resource with a position on a certain map. As the various attributes of work items and resources may vary over time it is important to see the class of functions $position_m$ as time dependent.

To formalise the notion of distance metric, a distance function is defined for each metric that yields the distance between a work item and a resource according to that metric.

Definition 4 (Distance function). Let W and R be the set of work items and resources. Let D be the set of available distance metrics. For each distance metric $d \in D$, there exists a function distance_d : $W \times R \rightarrow [0,1]$ that returns a number in the range [0,1] capturing the distance between work-item $w \in W$ and resource $r \in R$ with respect to metric d.¹⁰

Given a certain metric d and a resource r, the next work item r should perform is a work item w for which the value $distance_d(w, r)$ is the closest to 1 among all offered work items.

3.2 Available Metrics

In Table 2 a number of general-purpose distance metrics are informally explained. These are all provided with the current implementation. Due to the limited space, we will provide more details for only one of these distance metrics. The metric chosen combines the familiarity of a resource with a certain work item and the familiarity of other resources that are able to execute that work item. In order to formalise this notion, two auxiliary functions are introduced.

past_execution(w,r) yields the weighted mean of the past execution times of the last *h*-th work items performed by *r* among all work item siblings of w. In this context, the past execution time of work item w' is defined as the duration that elapsed between its assignment to *r* and its successful completion. Let $time_i(w, r)$ be the execution time of the *i*-th last work item

¹⁰ Please note the value 1 represents the minimum distance while 0 is the maximum.

Table 2. Distance Metrics currently provided by the implementation

Metric	Returned Value
$distance_{Familiarity}(w, r)$	How familiar is resource r with performing work item w . This can be
	measured through the number of sibling work items the resource has
	already performed.
$distance_{Geo_Distance}(w, r)$	How close is resource r to work item w compared to the closest resource
	that was offered w . For the closest resource this distance is 1. In case
	w does not have a specific GPS location where it should be executed,
	this metric returns 1 for all resources.
$distance_{Popularity}(w, r)$	The ratio of logged-in resources having been offered w to all logged-
	in resources. This metric is independent from resource r making the
	request.
$distance_{Urgency}(w, r)$	The ratio between the current timestamp and the latest timestamp
	when work item w can start but is not likely to expire. The latter
	timestamp is obtained as the difference between w_e , the latest times-
	tamp when w has to be finished without expiring, and w 's estimated
	duration. This estimation is based on past execution of sibling work
	items of w by r .
$distance_{Past_Execution(w,r)}$	How familiar is resource r with work item w compared to the familiar-
	ity of all other resources that w has been offered to. More information
	about this metric is provided in the text.

among w's siblings performed by r, then:

$$past_execution(w,r) = \frac{\sum_{i=1}^{j_{(w,r,h)}} \alpha^{i-1} \cdot time_i(w,r)}{\sum_{i=1}^{j_{(w,r,h)}} \alpha^{i-1}}$$
(1)

where constant $\alpha \in [0, 1]$ and value $j_{(w,r,h)}$ is the minimum between a given constant h and the number of sibling work items of w performed by r. Both h and α have to be tuned through testing. If value $j_{(w,r,h)}$ is equal to zero, $past_execution(w,r)$ is assumed to take an arbitrary large number.¹¹ The intuition behind this definition stems from the fact that more recent executions should be given more consideration and hence weighted more as they better reflect resources gaining experience in the execution of instances of a certain task.

 $\operatorname{Res}(\mathbf{w})$ returns all currently logged-in resources that have been offered w:

$$Res(w) = \{r \in R \mid w \text{ is offered to } r\}.$$

Using these auxiliary functions the following metric can be defined:

$$distance_{Relative_Past_Execution}(w,r) = \frac{1/past_execution(w,r)}{\sum_{r' \in Res(w)} 1/past_execution(w,r')}.$$
 (2)

Again, space considerations prevent us from providing an in-depth explanation of this definition and instead, we just provide some intuition. First observe that

 $[\]overline{}^{11}$ Technically, we set it as the maximum floating value.

if exactly one resource r exists capable of performing work item w, then the equation yields one. If n resources are available and they roughly have the same familiarity with performing work item w, then for each of them the distance will be about 1/n. It is clear then that as n increases in value, the value of the distance metric approaches zero. If on the other hand many resources exist that are significantly more effective in performing w than a certain resource r, then the value of the denominator increases even more and the value of the metric for w and r will be closer to zero.

4 Implementation

The general framework described in the previous section has been operationalised through the development of a component that can be plugged into the YAWL system. The YAWL environment is an open source PAIS, based on the workflow patterns¹², using a service-oriented architecture. The YAWL engine and all other services (work list handler, web-service broker, exception handler, etc.) communicate through XML messages. The YAWL work list handler was developed as a web application. In its graphical interface different tabs are used to show the various queues (e.g. offered work items). The visualisation framework can be accessed through a newly introduced tab and is implemented as a Java Applet.

Section 4.1 illustrates some of the visualisation features provided by the implementation, whereas Section 4.2 focusses on how the component fits within the YAWL architecture.

4.1 The User Interface

The position and distance functions represent orthogonal concepts that require joint visualisation for every map. The position function for a map determines where work items and resources will be placed as dots, while the distance function will determine the colour of work items. Conceptually, work item information and resource information is split and represented in different layers. Users can choose which layers they wish to see and in case they choose both layers which of them should overlay the other.

Work-item Layer. Distances can be mapped to colours for work items through a function $colour : [0, 1] \rightarrow C$ which associates every metric value with a different colour in the set C. In our implementation colours range from white to red, with intermediate shades of yellow and orange. When a resource sees a red work item this could for example indicate that the item is very urgent, that it is one of those most familiar to this resource, or that it is the closest work item in terms of its geographical position. While the colour of a work item can depend on the resource viewing it, it can also depend on which state of the lifecycle it is in. Special colours are used to represent the various states of the work item lifecycle and Table 3 provides an overview. The various rows correspond to the various states and their visualisation. Resources can filter work items depending on the

¹² www.workflowpatterns.com

Allocated to a single resource	Purple.		
Started	Black.		
Suspended	The same as for offered.		
Failed	Grey.		
Completed	Work item is not shown.		

Table 3. Visualisation of a work item depending on its state in the life cycle.

state of items. This is achieved through the provision of a checkbox for each of the states of Table 3. Several checkboxes can be ticked. There is an additional checkbox which allows resources to see work items that they cannot execute, but they are authorised to see.

Resources may be offered work items whose positions are the same or very close. In such cases their visualisations may overlap and they are grouped into a so-called "joint dot". The diameter of a joint dot is proportional to the number of work items involved. More precisely, the diameter D of a joint dot is determined by $D = d(1 + \lg n)$, where d is the standard diameter of a normal dot and n is the number of work items involved. Note that we use a logarithmic (lg) scaling for the relative size of a composite dot.

Combining several work items int a single dot raises the question of how the distance of this dot is determined. Four options are offered for defining the distance of a joint dot, one can take a) the maximum of all the distances of the work items involved, b) their minimum, c) their median, or d) their mean. When a resource clicks on a joint dot, all work items involved are enumerated in a list and they are coloured according to their value in terms of the distance metric chosen.

Resource Layer. When a resource clicks on a work item the positions of the other resources to whom this work item is offered are shown. Naturally this is governed by authorisation privileges and by the availability of location information for resources for the map involved.

Resource visualisation can be customised so that a resource can choose to see a) only herself, b) all resources, or c) all resources that can perform a certain work item. The latter option supports the case where a resource clicks on a work item and wishes to see the locations of the other resources that can do this work item.

4.2 Architectural Considerations

Figure 1 shows the overall architecture of the visualisation framework and the connections with other YAWL components. Specifically, the visualisation framework comprises:

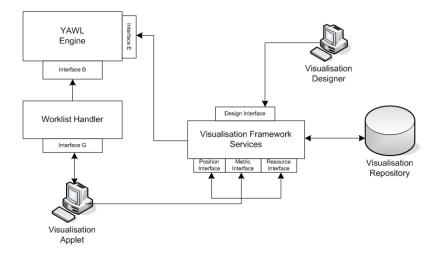

Fig. 1. Position of the visualisation components in the YAWL architecture.

- The Visualisation Applet is the client-side applet that allows resources to access the visualisation framework and it resides as a separate tab in the work-list handler.
- The Visualisation Designer is used by special administrators in order to define and update maps as well as to specify the position of work items on defined maps. Designers can define positions as fixed or as variable through the use of XQuery. In the latter case, an XQuery expression is defined that refers to case variables. This expression is evaluated at run time when required.
- **Services** is the collective name for modules providing information used to depict maps and to place work items (e.g. URLs to locate map images, work item positions on various maps).

The YAWL engine is at the heart of the YAWL environment. It determines which work items are enabled and can thus be offered for execution and it handles the data that is involved. While the YAWL engine offers a number of external interfaces, for the visualisation component interfaces B and E are relevant. Interface B is used, for example, by the work list handler to learn about work items that need to be offered for execution. This interface can also be used for starting new cases. Interface E provides an abstraction mechanism to access log information, and can thus e.g. be used to learn about past executions of siblings of a work item. In particular one can learn how long a certain work item remained in a certain state.

The *work list handler* is used by resources to access their "to-do" list. The standard version of the work list handler provides queues containing work items in a specific state. This component provides interface G which allows other components to access information about the relationships between work items and resources. For example, which resources have been offered a certain work item

or which work items are in a certain state. Naturally this component is vital to the Visualisation Applet.

In addition to interface G, the Visualisation Applet also connects to the *Services* modules through the following interfaces:

- The Position Interface provides information about maps and the positioning of work items on these maps. Specifically, it returns an XQuery over the YAWL net variables that the Visualisation Applet has to compute. The work list handler needs to be consulted to retrieve the current values of these variables.
- **The Metric Interface** provides information about available metrics and their values for specific work item resource combinations.
- The Resource Interface is used to update and retrieve information concerning positions of active resources on maps.

The visualisation framework was integrated into the standard work list handler of YAWL through the addition of a JSP (Java Server Page).

All of the services of the visualisation framework share a repository, referred to as *Visualisation Repository* in Figure 1, which stores, among others, XQueries to compute positioning information, resource locations in various maps, and names and URLs of maps. Services periodically retrieve log data through Interface E in order to compute distance metric values for offered work items. For instance, to compute the metric *Relative Past Execution* (Equation 2) for a certain resource, one can see from Equation 1 that information is required about the h past executions of sibling work items performed by that resource.

To conclude this section, we would like to stress that the approach and implementation are highly generic, i.e., it is relatively easy to embed the visualisation framework in another PAIS.

5 Example: Emergency Management

In this section we are going to illustrate a number of features of the visualisation framework by considering a potential scenario from emergency management. This scenario stems from a user requirement analysis conducted in the context of a European-funded project [2]. Teams are sent to an area to make an assessment of the aftermath of an earthquake. Team members are equipped with a laptop and their work is coordinated through the use of a PAIS.

The main process of workflow for assessing buildings is named *Disaster Management*. The first task *Assess the affected area* represents a quick on-the-spot inspection to determine damage to buildings, monuments and objects. For each object identified as worthy of further examination an instance of the sub-process *Assess every sensible object* (of which we do not show the actual decomposition for space reasons) is started as part of which a questionnaire is filled in and photos are taken. This can be an iterative process as an evaluation is conducted to determine whether the questionnaire requires further refinement or more photos need to be taken. After these assessments have finished, the task *Send data to*

the headquarters can start which involves the collection of all questionnaires and photos and their subsequent dispatch to headquarters. This information is used to determine whether these objects are in imminent danger of collapsing and if so, whether this can be prevented and how that can be achieved. Depending on this outcome a decision is made to destroy the object or to try and restore it.

For the purposes of illustrating our framework we assume that an earthquake has occurred in the city of Brisbane. Hence a number of cases are started by instantiating the *Disaster Management* workflow described above.

Each case deals with the activities of an inspection teams in a specific zone. Figure 2 shows three maps. In each map, the dots refer to work items. Figure 2(a) shows the main process of the *Disaster Management* workflow, including eight work items. Dots for work items which are instances of tasks *Assess the affected area* and *Send data to the headquarter* are placed on top of these tasks in this figure. Figure 2(b) shows the decomposition of the *Assess every sensible object* sub-net. Here also eight work items are shown. No resources are shown in these diagrams. Note that on the left-hand side is shown a list of work items that are not on the map. For example, the eight work items shown in the map in Figure 2(a) appear in the list of "other work items" in Figure 2(b).

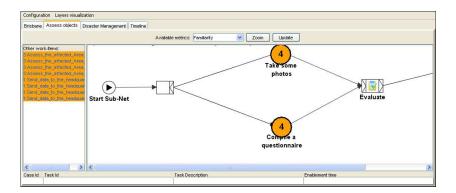

Figure 2(a) uses the urgency distance metric to highlight urgent cases while Figure 2(b) uses the familiarity metric to highlight cases closer to the user in terms of earlier experiences.

As another illustration consider Figure 2(c) where work items are positioned according to their deadlines. This can be an important view in the context of disaster management where saving minutes may save lives. In the map shown, the x-axis represents the time remaining before a work item expires, while the y-axis represents the case number of the case the work item belongs to. A work item is placed at location $(100 + 2 * \tilde{x}, 10 + 4 * \tilde{y})$ on that map, if \tilde{x} minutes are remaining to the deadline of the work item and its case number is \tilde{y} . In this example, work items are coloured in accordance with the *popularity* distance metric.

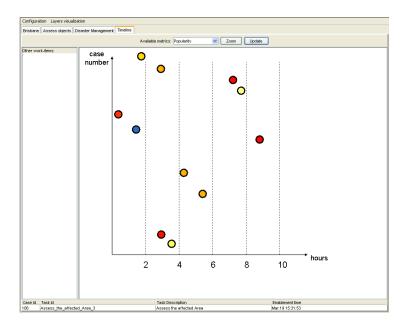

Figures 3 and 4 show some screenshots of a geographical map of the city of Brisbane. Note that geographic maps are plain JPG images and have been obtained by capturing some screen shots from Google Maps. On these maps, work items are placed at the location where they should be executed. If their locations are so close that their corresponding dots overlap, a larger dot (i.e., a joint-dot) is used to represent the work items involved and the number inside corresponds to the number of these items. The green triangle is a representation of the resource whose work list is visualised here. Work items for tasks Assess the affected area and Send data to the headquarters are not shown on the map as they can be performed anywhere. In this example, dots are coloured according to the familiarity distance metric. A dot that is selected as focus obtains a blue colour and further information about the corresponding work item is shown at the bottom of the screen (as is the case for work item Take_Photos_4 in Figure 3(b)).

(a) When a triangle is selected, the corresponding resources and offered work items are shown

(b) When zooming in, clustered work items and resources are separated

 ${\bf Fig. \, 4. \ Further \ examples \ of \ Geographic \ Maps \ for \ Disaster \ Management.}$

One can click on a dot and see the positions of other resources that have been offered the corresponding work item. For example, by clicking on the dot representing work item $Take_Photos_4$, other resources, represented by triangles, are shown (see Figure 3(b)). As for work items, overlapping triangles representing resources are combined. For examples, the larger triangle shown in Figure 3(b) represents two resources.

Figure 4(a) shows the screen shot after clicking on the joint triangle. A resource can thus see the list of resources associated with this triangle. By selecting one of the resources shown in the list, the work items offered to that resource can be seen. The colour of these work items is determined by their value for the chosen distance metric. A zooming feature is also provided. Figure 4(b) shows the result of zooming in a bit further on the map of Figure 4(a). As can be seen, no dots nor any triangles are overlapping anymore.

6 Conclusions

In this paper a general visualisation framework is proposed that can aid users in selecting the "right" work item among a potentially large number of work items offered to them. The framework uses the "map metaphor" to show the locations of work items and resources. The "distance metaphor" is used to show which work items are "close" (e.g., urgent, similar to earlier work items, or geographically close). Both concepts are orthogonal and this provides a great deal of flexibility when it comes to presenting work to people. For example, one can choose a geographical map to display work items and resources and use a distance metric capturing urgency. The proposed framework was operationalised as a component of the YAWL environment. By using well-defined interfaces the component is generic so that in principle it could be exploited by other PAISs as well under the provision that they are sufficiently "open" and provide the required interface methods. The component is also highly configurable, e.g., it allows resources to choose how distances should be computed for dots representing a number of work items and provides customizable support for determining which resources should be visible. Our operationalisation does not rely on external services such as Google Maps for map visualisation support. Maps are just images on which dots representing work items are to be positioned. Hence our approach is not restricted to certain types of maps.

Finally, it should be pointed out that the implementation for the Visualisation Designer is still lacking. In the current evaluation, we manually updated the information stored in the Visualisation Repository by accessing tables in the DBMS. All other parts are fully operational.

Further research aims at connecting the current framework to geographical information systems and process mining tools like ProM [4]. Geographical information systems store data based on locations and process mining can be used to extract data from event logs and visualise this on maps, e.g., it is possible to make a "movie" showing the evolution of work items based on historic data.

Acknowledgements. The work was primarily conducted during a visit of Massimiliano de Leoni to the Business Process Management Group at Queensland University of Technology. His internship has been partly supported by the European Commission through the project FP6-2005-IST-5-034749 WORKPAD. The authors would like to thank Michael Adams for implementing certain required YAWL interfaces and for answering numerous questions. We also gratefully acknowledge Guy Redding for providing some code to connect to the YAWL interfaces.
